# Assignment 3: IBM-Project-10469-1664355350

**Problem Statement: Abalone Age Prediction** 

# **Description:**

Predicting the age of abalone from physical measurements. The age of abalone is determined by cutting the shell through the cone, staining it, and counting the number of rings through a microscope -- a boring and time-consuming task. Other measurements, which are easier to obtain, are used to predict age. Further information, such as weather patterns and location (hence food availability) may be required to solve the problem.

# **Importing Modules**

```
In [1]:
```

```
import pandas as pd
import seaborn as sns
import matplotlib.pyplot as plt
import numpy as np
```

### 1. Dataset has been downloaded

```
In [ ]:
```

```
#Name of the dataset: abalone.csv
```

### 2. Load the dataset into the tool

```
In [12]:
```

```
data=pd.read_csv("abalone.csv")
data.head()
```

### 3. Perform Below Visualizations.

# (i) Univariate Analysis

#### #

The term univariate analysis refers to the analysis of one variable. You can remember this because the prefix "uni" means "one." There are three common ways to perform univariate analysis on one variable: 1. Summary statistics – Measures the center and spread of values.

# (ii) Bi-Variate Analysis

#

Image result for bivariate analysis in python It is a methodical statistical technique applied to a pair of variables (features/ attributes) of data to determine the empirical relationship between them. In order words, it is meant to determine any concurrent relations (usually over and above a simple correlation analysis).

# (iii) Multi-Variate Analysis

### #

Multivariate analysis is based in observation and analysis of more than one statistical outcome variable at a time. In design and analysis, the technique is used to perform trade studies across multiple dimensions while taking into account the effects of all variables on the responses of interest.

### #

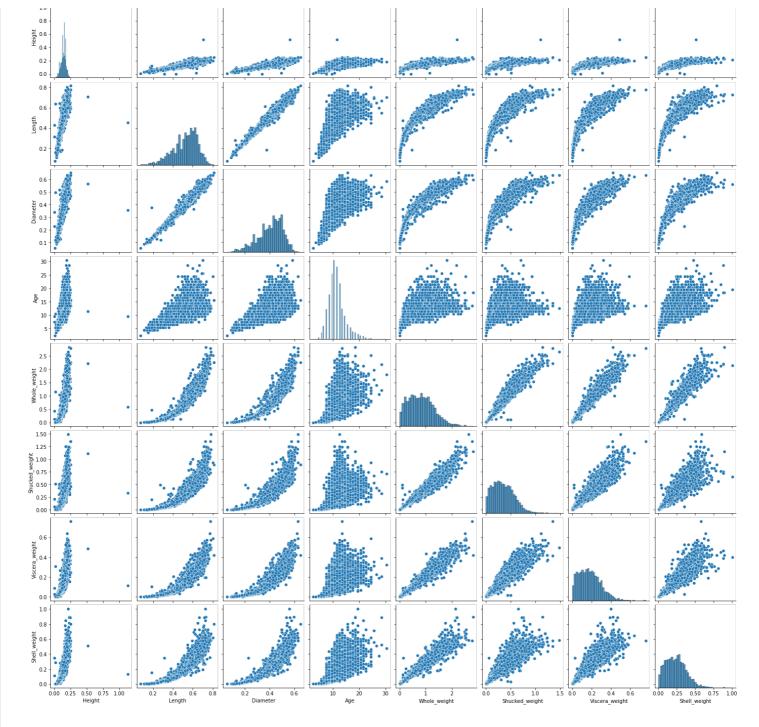

### **Pairplot**
